

# Inchworms

# Description

Inchworms are small insects that will 'inch' across plants and trees to get their main food, plant leaves. These slimy creatures are relatives of caterpillars except instead of turning into butterflies inchworms turn into moths.

# Habitat

Inchworms live everywhere in the world except in snowy biomes. You will find them mostly in gardens where trees and plants live. Some inchworms only live in some places because they only like certain plants or trees.

# Food

Inchworms eat lots and lots of leaves. Some eat only the lichen or pollen. Some even eat other small bugs.

# Lifecycle

Inchworms go through metamorphosis to turn into moths. The inchworms are actually baby moths called larvae. After the inchworm goes through that stage it goes into chrysalis to become pupae and then the adult moths
